

The camera:

First, the camera's location is plainly visible. It would have been easy for the killers to destroy it or avoid it entirely. Second, the camera sports a half-globe of tinted black glass to obscure the direction in which it aims. There is no way to track the camera's movement without breaking the covering or shining an extraordinarily bright light directly at it. Neither happened. And yet the leader of the assailants perfectly framed her face and her trophies for the camera.

The dog:

There is an odd artifact in the upper left corner of those static images from time to time. By comparing multiple images, it becomes apparent that the anomaly appears to be the back leg of a dog. Minuscule differences in the gravel over time indicate a path. The technicians insist that while a stray dog was responsible for discovering the buried remains, there's no way the photo was triggered by an animal passing by the motion sensor every day. Whether or not the time-stamps are set to an accurate clock, they keep consistent time. That would mean the same animal was passing along the same path on the outskirts of the motion sensor's range. Every day. At the exact same time. Down to the second. That's a ridiculous conclusion. The first responder did report finding the first buried body due to the excavations of a nearby stray dog. However, the animal was not found by the time backup arrived on scene. Presumably it ran away into the countryside.
