

The Preserved bodies

Two grad students already threw up, we need an adult here.

The Stew

Four graves contain nothing except a foul, black jelly. Not even bones remain. Soil dating estimates their grave sites to be the most recent. Dr. Grace orders all other investigators away from those sites so her team can handle them, dressed in biohazard suits. She insists that only the Harvard team is equipped to glean actionable information from specimens suffering such advanced deterioration. While a body decomposing into sludge isn't uncommon, this "stew," as Grace calls it, has alarming properties. Its viscosity and surface tension kept the contents from leaking out of the trash bags the bodies were buried in. The thick gelatin takes the shape of its container. More disturbingly, the pitch-black substance experiences subtle ripples and bubbles whenever ungloved human flesh comes near it, almost like ferro-fluid in the presence of a magnet. It has no reaction to tools or any nonliving substance.

An examination of the stew at a microscopic level determines that the stuff can't definitively be said to have ever belonged to a human cell structure at all. The cause of the stew is anyone's guess. Further experiments only open more questions. Microbiological cultures that died on contact with the preserved bodies thrive and grow when exposed to the stew.

Redacted - no fucking way, this is unbelievable. Try the animal tests again?
